Patients with community-acquired pneumonia often present with cough, fever, chills, fatigue, dyspnea, rigors, and pleuritic chest pain. When a patient presents with suspected community-acquired pneumonia, the physician should first assess the need for hospitalization using a mortality prediction tool, such as the Pneumonia Severity Index, combined with clinical judgment. Consensus guidelines from several organizations recommend empiric therapy with macrolides, fluoroquinolones, or doxycycline. Patients who are hospitalized should be switched from parenteral antibiotics to oral antibiotics after their symptoms improve, they are afebrile, and they are able to tolerate oral medications. Clinical pathways are important tools to improve care and maximize cost-effectiveness in hospitalized patients. (Am Fam Physician 2006;73:442-50. Members of various family medicine departments develop articles for "Practical Therapeutics." This article is one in a series coordinated by the Department of Family Medicine at the University of Illinois at Chicago College of Medicine, Chicago, Ill. Guest editor of the series is Eric Henley, M.D., M.P.H.

Community-acquired pneumonia (CAP) is defined as pneumonia not acquired in a hospital or a long-term care facility. Despite the availability of potent new antimicrobials and effective vaccines,[1] an estimated 5.6 million cases of CAP occur annually in the United States.[2] The estimated total annual cost of health care for CAP in the United States is $8.4 billion.[2] *Table 1* presents an overview of CAP including definition, signs and symptoms, etiology, and risk factors.

Epidemiology

The epidemiology of CAP is unclear because few population-based statistics on the condition alone are available. The Centers for Disease Control and Prevention (CDC) combines pneumonia with influenza when collecting data on morbidity and mortality, although they do not combine them when collecting hospital discharge data. In 2001, influenza and pneumonia combined were the seventh leading causes of death in the United States,[3,4] down from sixth in previous years, and represented an age-adjusted death rate of 21.8 per 100,000 patients.[3] Death rates from CAP increase with the presence of comorbidity and increased age; the condition affects persons of any race or sex equally. The decrease in death rates from pneumonia and influenza are largely attributed to vaccines for vulnerable populations (e.g., older and immunocompromised persons).

Clinical Presentation

Pneumonia is an inflammation or infection of the lungs that causes them to function abnormally. Pneumonia can be classified as typical or atypical, although the clinical presentations are often similar. Several symptoms commonly present in patients with pneumonia.

TYPES OF CAP

Typical pneumonia usually is caused by bacteria such as *Streptococcus pneumoniae*. Atypical pneumonia usually is caused by the influenza virus, mycoplasma, chlamydia, legionella, adenovirus, or other unidentified microorganism. The patient's age is the main differentiating factor between typical and atypical pneumonia; young adults are more prone to atypical causes,[5,6] and very

young and older persons are more predisposed to typical causes.

SYMPTOMS

Common clinical symptoms of CAP include cough, fever, chills, fatigue, dyspnea, rigors, and pleuritic chest pain. Depending on the pathogen, a patient's cough may be persistent and dry, or it may produce sputum. Other presentations may include headache and myalgia. Certain etiologies, such as legionella, also may produce gastrointestinal symptoms.

Diagnosis

PHYSICAL EXAMINATION

Physical examination may reveal dullness to percussion of the chest, crackles or rales on auscultation, bronchial breath sounds,

TABLE 1
Overview of Community-Acquired Pneumonia

Definition
Lower respiratory tract infection in a nonhospitalized person that is associated with symptoms of acute infection with or without new infiltrate on chest radiographs

Clinical presentation
Temperature greater than 38°C (100.4°F)
Cough with or without sputum, hemoptysis
Pleuritic chest pain
Myalgia
Gastrointestinal symptoms
Dyspnea
Malaise, fatigue
Rales, rhonchi, wheezing
Egophony, bronchial breath sounds
Dullness to percussion
Atypical symptoms in older patients

Etiology
Bacterial
- Chlamydia species
- *Haemophilus influenzae*
- Legionella species
- *Moraxella catarrhalis*
- *Mycoplasma pneumoniae*
- *Staphylococcus aureus*
- *Streptococcus pneumoniae*

Viral
- Adenovirus
- Influenza A and B
- Parainfluenza
- Respiratory syncytial virus

Endemic fungi
- Blastomycosis
- Coccidioidomycosis
- Histoplasmosis

Risk factors
Age older than 65 years
Human immunodeficiency virus or immunocompromised
Recent antibiotic therapy or resistance to antibiotics
Comorbidities
- Asthma
- Cerebrovascular disease
- Chronic obstructive pulmonary disease
- Chronic renal failure
- Congestive heart failure
- Diabetes
- Liver disease
- Neoplastic disease

tactile fremitus, and egophony ("E" to "A" changes). The patient also may be tachypneic. A prospective study[7] showed that patients with typical pneumonia were more likely than not to present with dyspnea and bronchial breath sounds on auscultation.

RADIOGRAPHY

Chest radiography (posteroanterior and lateral views) has been shown to be a critical component in diagnosing pneumonia.[8] According to the latest American Thoracic Society (ATS) guidelines for the diagnosis and treatment of adults with CAP, "all patients with suspected CAP should have a chest radiograph to establish the diagnosis and identify complications (pleural effusion, multilobar disease)."[8] Chest radiography may reveal a lobar consolidation, which is common in typical pneumonia; or it could show bilateral, more diffuse infiltrates than those commonly seen in atypical pneumonia. However, chest radiography performed early in the course of the disease could be negative.

TABLE 2
Sensitivity and Specificity of Diagnostic Tests for CAP

Diagnostic tests by pathogen	*Sensitivity (%)*	*Specificity (%)*
Chlamydia		
Rapid PCR (sputum, BAL fluid)	30 to 95	> 95
Serology (fourfold rise in serum and convalescent titers)	10 to 100	—

LABORATORY TESTS

Historically, common laboratory tests for pneumonia have included leukocyte count, sputum Gram stain, two sets of blood cultures, and urine antigens. However, the validity of these tests has recently been questioned after low positive culture rates were found (e.g., culture isolates of *S. pneumoniae* were present in only 40 to 50 percent of cases).[9] Such low positive culture rates are likely due to problems with retrieving samples from the lower respiratory tract, previous administration of antibiotics, contamination from the upper airways, faulty separation of sputum from saliva when streaking slides or plates,[9] or viral etiology. Furthermore, sputum samples are adequate in only 52.3 percent of patients with CAP, and only 44 percent of those samples contain pathogens.[10] Nonetheless, initial therapy often is guided by the assumption that the presenting disease is caused by a common bacterial pathogen.

Findings[11] also cast doubt on the clinical utility of obtaining blood cultures from patients with suspected CAP. In a study[12] of CAP cases in 19 Canadian hospitals over a six-month period, positive blood cultures were obtained in only 5.2 to 6.2 percent of patients, including those with the most severe disease. Based on these findings, other researchers[13] concluded that a positive blood culture had no correlation with the severity of the illness or outcome. Another prospective study[10] showed that blood cultures were positive in only 10.5 percent of patients with pneumonia. Despite these and

other research findings, current ATS guidelines[8] recommend that patients hospitalized for suspected CAP receive two sets of blood cultures. Blood cultures, however, are not necessary for outpatient diagnosis.[8]

Legionella antigens were found in the urine of 48 percent of patients with suspected *Legionella pneumophila* serogroup 1 infection.[14] *Table 2*[2,8,11,13] includes the sensitivity and specificity of diagnostic tests for CAP.

Treatment

Initial treatment of CAP is based on physical examination findings, laboratory results, and patient characteristics (e.g., age, chronic illnesses, history of smoking, history of the illness).[15] Physicians should begin their treatment decisions by assessing the need for hospitalization using a prediction tool for increased mortality, such as the Pneumonia Severity Index *(Table 3*[15]*)*, combined with clinical judgment.[9]

OUTPATIENT VS. INPATIENT TREATMENT

Choosing between outpatient and inpatient treatment is a crucial decision because of the possible risk of death.[9,15,16] This decision not only influences diagnostic testing and medication choices, it can have a psychological impact on patients and their families. On average, the estimated cost for inpatient care of patients with CAP is $7,500. Outpatient care can cost as little as $150 to $350.[17-19] Hospitalization of a patient should depend on patient age, comorbidities, and the severity of the presenting disease.[9,20]

Physicians tend to overestimate a patient's risk of death[14]; therefore, many low-risk patients who could be safely treated as outpatients are admitted for more costly inpatient care. The Pneumonia Severity Index *(Table 3*[15]*)* was developed to assist physicians in identifying patients at a higher risk of complications and who are more likely to benefit from hospitalization.[9,15,16] Investigators developed a risk model based on a prospective cohort study[16] of 2,287 patients with CAP in Pittsburgh, Boston, and Halifax, Nova Scotia. By using the model, the authors found that 26 to 31 percent of the hospitalized patients were good outpatient candidates, and an additional 13 to 19 percent only needed brief hospital observation. They validated this model using data[17] from more than 50,000 patients with CAP in 275 U.S. and Canadian hospitals.[15-17,21,22]

TABLE 3
Pneumonia Severity Index

Patient Characteristics	*Points*
Demographics	
Male	Age (years)
Female	Age (years) – 10
Nursing home resident	+ 10
Comorbid illness	
Neoplastic disease	+ 30
Liver disease	+ 20
Congestive heart failure	+ 10
Cerebrovascular disease	+ 10

> 130	High	V	29.2 (9,333)	Inpatient

Information from reference 15.

Although the Pneumonia Severity Index can serve as a general guideline for management, clinical judgment should always supersede the prognostic score.[9]

PHARMACOTHERAPY

The primary goals of pharmacotherapy for patients with CAP include eradicating the causative pathogens, resolving the clinical signs and symptoms, minimizing hospitalization, and preventing reinfection.[23-27] Physicians should choose a medication based on the pharmacokinetic profile, adverse reactions, drug interactions, and cost-effectiveness.[23-27] Further, patient evaluation should focus on severity of illness, patient age, comorbidities, clinical presentation, epidemiologic setting, and previous exposure.[9] The majority of patients with CAP are treated empirically based on the most common pathogen(s) associated with the condition.[23-27]

Management of CAP

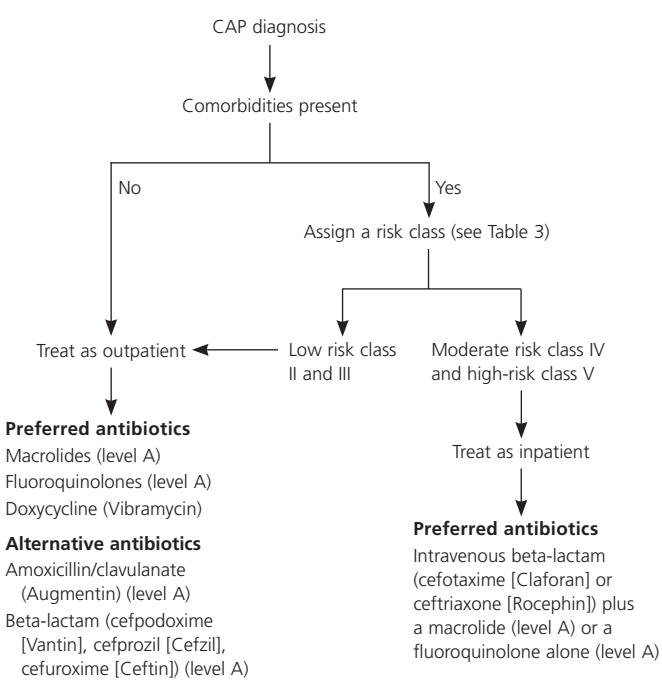

Figure 1. Algorithm for the management of CAP. (CAP = community-acquired pneumonia.)

Adapted with permission from Fish D. Pneumonia. PSAP, Pharmacotherapy Self-Assessment Program. Kansas City, Mo.: American College of Clinical Pharmacy, 2002:202.

Consensus guidelines from ATS,[8] Infectious Diseases Society of America,[9] and Canadian Guidelines for the Initial Management of Community-Acquired Pneumonia[28] *(Figure 1[6])* recommend initial empiric therapy with macrolides, fluoroquinolones, or doxycycline (Vibramycin). A fourth guideline[29] developed by the Therapeutic Working Group of the CDC, however, recommends using fluoroquinolones sparingly because of resistance concerns.

Although data are limited on duration of CAP therapy, current research[30] recommends seven to 10 days of therapy for *S. pneumoniae* and 10 to 14 days of therapy for *Mycoplasma pneumoniae* and *Chlamydia pneumoniae*. After a hospitalized patient is clinically stable (i.e., temperature less than 37.8° C [100.0° F], pulse under 100 beats per minute, respiratory rate below 24 breaths per minute, systolic blood pressure above 90 mm Hg, and blood oxygen saturation over 90 percent) and able to tolerate oral intake, the patient may be treated with oral antibiotics for the remainder of the therapy course. This can save money and allow for earlier hospital discharge, which minimizes a patient's risk of hospital-acquired infection.

Pneumococcal Resistance

S. pneumoniae, which accounts for 60 to 70 percent of all bacterial CAP cases, can affect all patient groups and can cause a fatal form of CAP. The alarming rate of resistance to many commonly used antibiotics raises great concern. Penicillin-resistant *S. pneumoniae* was uncommon in the early 1990s but has since become increasingly prevalent.[29,31]

Resistant strains are classified as having intermediate or high-level resistance. Surveillance data in the United States[30] revealed that, overall, pneumococcal strains had a 28 percent immediate resistance rate and a 16 percent high-level resistance rate. Decreased susceptibility to other commonly used antibiotics has also been observed *(Table 4[32])*.[29-31] The clinical importance of these data is questionable because recruiting patients infected with resistant pathogens for clinical trials is difficult. Furthermore, available outcomes on the treatment of

TABLE 4
Patterns of Resistance to Antibiotics in North America*

Information from reference 32.

pneumonia caused by resistant pneumococcal strains are conflicting.[30]

The CDC and others recommend outpatient oral empirical antibiotics with a macrolide, doxycycline, or an oral beta-lactam (amoxicillin, cefuroxime [Ceftin], or amoxicillin/clavulanate [Augmentin]) or inpatient treatment with an intravenous beta-lactam (cefuroxime, ceftriaxone [Rocephin], cefotaxime [Claforan]) or a combination of ampicillin/sulbactam (Unasyn) with a macrolide *(Figure 1*[6]*)*.[28,29] Conservative use of new fluoroquinolones (levofloxacin [Levaquin], gatifloxacin [Tequin], moxifloxacin [Avelox]) also is recommended to minimize resistance patterns.[28,29] The new fluoroquinolones (minimum inhibitory concentration: 4 mcg per mL or greater) should be used only when patients have failed recommended first-line regimens, are allergic to alternative agents, or have a documented infection with highly drug-resistant pneumococci such as those resistant to penicillin.[28,29]

Cost of Antimicrobial Therapy

Economic pressures have accentuated the focus on reducing health care costs and utilizing resources while maintaining or improving quality of care.[31] These pressures are exacerbated by the growing resistance of *S. pneumoniae* to penicillin.[31,32] This pattern of resistance increases the cost of treatment because of prolonged hospitalization, relapses, and the use of more expensive antibacterial agents.[33-37]

REDUCING COSTS

Numerous methods for reducing costs when treating patients with bacterial infections can be applied to CAP *(Table 5)*. Choosing monotherapy instead of combination therapy

TABLE 5
Strategies for Reducing the Cost of Antibiotic Therapy

Administration
Use the shortest appropriate course possible.
Switch from parenteral to oral antibiotics as soon as clinically appropriate.
Adverse events
Avoid agents with serious or costly adverse effects.
Avoid agents known to induce resistance.
Drug cost
Compare low impact with total hospital costs (but significant to pharmacy costs).
Hospitalization
Use knowledge of local resistance to initiate early therapy with appropriate spectrum agent (few data available).
Consider availability and cost-effectiveness of intravenous versus oral administration.
Monitoring
Avoid agents that require therapeutic monitoring or laboratory safety tests.
Pharmacotherapy
Use long-acting antibiotics.
Use potent bactericides.
Avoid antibiotics with poor tissue penetration.

TABLE 6
Antimicrobial Therapies for CAP

Agent	*Dosage**	*Cost per course† (generic)*	*Common adverse reactions‡*
Cephalosporins			Mild diarrhea
Cefotaxime (Claforan)	1 g IV every six to eight hours	$355 (330)	Rash
Cefpodoxime (Vantin)	200 mg orally twice per day	124 (110)	
Cefprozil (Cefzil)	500 mg orally twice per day	192	
Ceftriaxone (Rocephin)	1 g IV every 24 hours	392	
Cefuroxime (Ceftin)	500 mg orally twice per day	219 oral	
	0.75 to 1.5 g IV every eight hours	250 to 358 IV	
Clindamycins			Mild diarrhea
Clindamycin (Cleocin)	300 mg orally every six hours	238 (148 to 168) oral	Abdominal pain
	600 mg IV every eight hours	250 IV	Pseudomembranous colitis
			Rash
Fluoroquinolones			Mild diarrhea
Gatifloxacin (Tequin)	400 mg orally or IV once per day	98 oral, 382 IV	Nausea
Levofloxacin (Levaquin)	500 mg orally or IV once per day	56 oral, 438 IV	Vomiting
Moxifloxacin (Avelox)	400 mg orally once per day	107	Constipation
			Dizziness
			Headache
Macrolides			Mild diarrhea
Azithromycin (Zithromax)	500 mg orally for one dose, then 250 mg once per day for four doses	49 to 60 oral	Nausea
			Vomiting
	500 mg IV every 24 hours	295 IV	Abdominal pain
Clarithromycin (Biaxin)	500 mg orally twice per day	96	Rash
Erythromycin	500 mg orally every six hours	17 (8 to 10) oral	
	500 to 1,000 mg IV every six hours	(167) IV	
Penicillins			Mild diarrhea
Amoxicillin	500 mg orally every eight hours	4 (4 to 8)	Nausea
	875 mg orally every 12 hours	20 (18 to 19)	Vomiting
Amoxicillin/clavulanate (Augmentin)	875 mg/125mg orally every 12 hours	166 (110 to 115)	Rash
Penicillin G	1 to 3 mU IV every four hours	(273)	
Penicillin V	500 mg orally four times per day	15 (9 to 15)	
Tetracyclines			Mild diarrhea
Doxycycline (Vibramycin)	100 mg orally twice per day	102 (16 to 21)	Nausea
			Vomiting

reduces costs associated with administering an antibacterial.[33-37] Using agents with longer half-lives allows for once-daily administration, which in turn leads to improved compliance and outcomes and decreased costs.[33-37] In addition, transitioning patients to oral therapy as soon as they are clinically stable can significantly reduce the length of hospitalization—the major contributing factor to health care costs.[33-37]

COST-EFFECTIVE CARE

When choosing a treatment, it is essential to compare costs and outcomes of all recommended drug therapies.[31] *Table 6*[6] includes the costs of and common adverse reactions to antimicrobial therapies for CAP.

The goal of a formal pharmacoeconomic assessment is to enhance overall patient care using available resources. The evaluation should lead to a decision that will maximize the value of health care services, not simply reduce the costs of drug therapy. For instance, a particular drug may be more expensive, but it may also be more effective, thus lowering overall costs. Another drug may have a higher rate of treatment failures, creating added costs associated with managing the failures. The overall cost of each therapy should be obtained by comparing the end cost with the probability of achieving a positive outcome. Depending on the relative costs associated with treatment failures compared with the costs of cures, the decision to choose one agent over another may change.

The best way to apply cost-saving approaches to the treatment of patients with CAP is by using a clinical pathway.[38] This is a method of facilitating multidisciplinary patient care by moving processes of care sequentially through various stages, within specified time frames, toward a desired outcome. These pathways should be specific to each institution, taking into account resistance rates in the community and encouraging the use of the most active, cost-effective agents to produce rapid, positive clinical outcomes.[31,39]
